

A Study of the Survival and Growth of a Fungal Species under Different Conditions

- The fungal species under study has been associated with grapevine decline.
- The study includes separate experiments to test the effect of temperature, water potential, and PH level on growth of a fungal species. Aim to find effective control strategies.
- Each experiment was a complete randomized design with three to four replications for each level of treatment. The experiment was repeated once (total two trials).

A Study of the Survival and Growth of a Fungal Species under Different Conditions

- The influence of water potential on colony growth was determined by adding sucrose, KCL, NaCL or Glycerol at appropriate concentration to generate different osmotic potentials, which reflect water's tendency to move across a membrane from a solution with lower solute concentration to one with higher solute concentration.
- After 7 days colony diameter was measured along two axes perpendicular to one another and the average of the two diameters was recorded as the colony diameter.

A Study of the Survival and Growth of a Fungal Species under Different Conditions

- For two individual projects
 - Project 1: Temperature experiment and PH experiment
 - Project 2: Water potential experiment

A Study of the Survival and Growth of a Fungal Species under Different Conditions

- Objectives:

1. Want to test if

- Fungi grows the same in different temperatures
- Fungi grows the same in different PH value
- Fungi grows the same in different water potential using different solutes

2. want to fit curves to show how colony diameter changes with temperature, water potential or PH value ([see examples below in the reference paper](#)).
